Background: The accurate evaluation of disease activity in Crohn's disease is important in treatment of the disease and monitoring the response. CT enterography is a useful imaging modality reflecting the enteric inflammation as well as extramural complications.

Objectives: To evaluate the correlation of CT enterographic findings of active Crohn's disease with the Crohn's Disease Activity Index (CDAI) and CRP.

Patients & Methods: 50 CT enterographies in 39 patients with Crohn's disease in the small bowel were enrolled in our study. CDAI was assessed through clinical or laboratory variables. Multiple CT parameters including mural hyper-enhancement, mural thickness, mural stratification, comb sign and mesenteric fat attenuation were examined with four-point scale. The presence of enhanced lymph nodes, or fatty proliferation, sinus or stricture, abscess and fistula were also examined. The correlation with CDAI

Notes:
