Abstract

Background: Success rate of laparoscopic sleeve gastrectomy (SG) depends on disease and patient characteristics that are yet to be fully established.

Objectives: To evaluate which patient characteristics influence the success of SG.

Setting: National bariatric reference centre at a Public Hospital.

Methods: A retrospective study was performed based on prospectively collected data of patients who had bariatric surgery at our institution, during a 5 year period. Patients with 12 or more months of follow-up were included. We analyzed data from 133 SG. Seventy-nine percent of the patients were female with a median age of 46 years, a median baseline Body Mass Index (BMI) of 41 kg/m² and a mean of 2.5 out of 7 comorbidities.

Results: After the first year, the mean percentage Excess Weight Loss (%EWL) was 69.3%, the mean change in BMI was -11.8 kg/m² and the mean % total body weight loss was 27.4%. Surgical success (%EWL > 50%) was achieved in 82% of the patients, with significant improvement or resolution of comorbidities (follow-up rate 76%-88%). We found statistical significant differences with baseline BMI (p<0.0001), with OSA (p<0.0001), with age (p=0.04) and with the number of comorbidities (p=0.05). Higher baseline characteristics implicated less %EWL. The presence of HTN or arthropathy and being a volume eater or a sweet eater did not influence surgical success (p=0.01).

Conclusions: SG is an effective surgical treatment for obesity. After one year the majority of patients had surgical success and major comorbidities were mitigated or resolved. Success was influenced by specific patient and disease characteristics.

Introduction

Obesity is a global public health problem, with a prevalence of 30% in the world. It is a complex disease with multiple etiologies, including genetic, environmental, and behavioral factors. The pathogenesis of obesity involves an imbalance between energy intake and energy expenditure, leading to the accumulation of excess adipose tissue. Obesity is associated with a high risk of developing comorbidities, such as type 2 diabetes, hypertension, and cardiovascular disease. Bariatric surgery, including laparoscopic sleeve gastrectomy (SG), has emerged as an effective treatment for obesity and its associated comorbidities. SG involves the removal of a portion of the stomach, resulting in a reduced capacity for food intake and altered gut hormones that regulate appetite and metabolism. The success of SG is influenced by various patient characteristics, including baseline BMI, age, and the presence of comorbidities. This study aims to evaluate the success rate of SG and the influence of patient characteristics on the outcome.

The purpose of this study was to evaluate the success rate of laparoscopic sleeve gastrectomy (SG) and the influence of patient characteristics on the outcome. The study was conducted in a tertiary care center, which is a national bariatric reference center. The study included 133 patients who underwent SG between 2012 and 2017. The patients were followed up for a minimum of 12 months. The primary outcome was the percentage of excess weight loss (%EWL) at 1 year. Secondary outcomes included the resolution of comorbidities, such as type 2 diabetes, hypertension, and obstructive sleep apnea (OSA). The study found that the mean %EWL at 1 year was 69.3%. The mean change in BMI was -11.8 kg/m² and the mean % total body weight loss was 27.4%. Surgical success (%EWL > 50%) was achieved in 82% of the patients. We found statistical significant differences with baseline BMI (p<0.0001), with OSA (p<0.0001), with age (p=0.04) and with the number of comorbidities (p=0.05). Higher baseline characteristics implicated less %EWL. The presence of HTN or arthropathy and being a volume eater or a sweet eater did not influence surgical success (p=0.01).
