

Introduction

Immune checkpoint molecules are one of the most well-studied and clinically targeted molecules in immunology. They play a critical role in regulating the immune response, and their dysregulation can lead to various autoimmune diseases and cancer. Inhibitory checkpoint molecules, such as CTLA-4 and PD-1, are known to suppress the immune response, while co-inhibitory molecules, such as HVEM and VISTA, are thought to have a more complex role in immune regulation. Understanding the function of these molecules is essential for developing new immunotherapies for cancer and autoimmune diseases.

Description

Immune checkpoint molecules: key regulators of immune activation

Immune checkpoint molecules are one of the most well-studied and clinically targeted molecules in immunology. They play a critical role in regulating the immune response, and their dysregulation can lead to various autoimmune diseases and cancer. Inhibitory checkpoint molecules, such as CTLA-4 and PD-1, are known to suppress the immune response, while co-inhibitory molecules, such as HVEM and VISTA, are thought to have a more complex role in immune regulation. Understanding the function of these molecules is essential for developing new immunotherapies for cancer and autoimmune diseases.
