The Infuence of Organizational Respect on Job Satisfaction in the Human Services: Findings from a New York State Multi-Site Job Satisfaction Cross-Sectional Survey – A Short Commentary

Rivka A. Edery*

MSW, LCSW, Psychotherapist, Private Practice, USA

INTRODUCTION

is article is a summary discussing the author's conceptualized and implemented Master's research project for: Fordham University Graduate School of Social Service, May 2009: " e in uence of organizational respect on job satisfaction in the human services". e ndings from a New York State-based multi-site job satisfaction cross-sectional survey design, drawing from a larger study, which utilized a longitudinal, quasi-experimental design.

is research explored the relationship between respect and job satisfaction from a sample of 1,216 of nursing home sta . e following hypothesis has guided this study: respect on the job will be positively related to job satisfaction, when tenure (length of time employed by current employer obtained by Human Resources), site (location of facility), a ect (Employee's personality), and subgroups (professional and paraprofessionals) of nursing home sta , are controlled for.

e purpose of publishing this article is to contribute to the e orts made to support public organizations in being less bureaucratic and more result-oriented, accountable, and customer driven (Park, 2017). A major problem in quality of care is nursing home sta turnover, which has been an acute problem in the nursing home industry for decades (Donoghue & Castle, 2006). Most research on nursing sta turnover links turnover to individual explanations such as job satisfaction (Curtis, 2007). Appropriate sta ng allows nurses to provide the necessary quality of care, as well as to improve nursing job satisfaction. Nurses continue to identify that improving their work environment will improve job satisfaction, which is the most important solution to resolving the nursing shortage (Krueger, 2002). Respect is perceived in terms of (1) inclusion within a group captured in terms of perceived liking (Branscombe et al., 2002); (2) fair treatment (e.g. Huo & Molina, 2006); (3) appraisal of qualities (Prestwich & Lalljee, 2009).

Respect manifested in nursing homes, a reliable in uencing variable for improving employee job satisfaction, would begin with organizational leadership shi ing their management approach from a predominately authoritarian one, to more of a partnership

model. Such a respectful management style would encompass a social dynamic that is supportive and inclusive of their employees, valuing how such a partnership with nursing sta in uences job satisfaction, and ultimately, patient satisfaction. ere are necessary steps to take if such a management approach is not already in existence. As a starting point, management would need to e ect a cultural transformation that is nurturing to a collaborative environment. Without respect for collaboration, a hierarchy will most likely be the dominating management approach (Potter, 2017).

An organization that has genuine respect for all employees, thereby remaining competitive, would reveal the following critical components: 1) shared core values between management and all employees, 2) respect as an organizational strength, including employee retention, 3) respect in the workplace is a signi cant work/ life issue, 4) prioritizing treating all sta equitably, with dignity and politeness, 5) recognizing the whole person, consistently, thereby fully engaging them. (Prince, 2000).

is study was designed and implemented by the research sta of a large, long-term health care facility for the elderly, Jewish Home and Hospital Lifecare System (JHH). JHH is comprised of three campuses: Manhattan, the Bronx and Westchester. ese campuses include forty-seven units, serving approximately 1600 elderly nursing home residents. e participants were all nursing home sta , from 13 units across the three sites of the organization. All sta , from every level of the organization, that was on the study units for two or more months, was asked to voluntarily ll out questionnaires. e author did not perform any analyses comparing the di erent study sites.

e ndings were from the quantitative component of a selfadministered questionnaire (N = 216). e data were drawn from a larger study which utilized a longitudinal, quasi-experimental design. Job satisfaction was measured with the Alliance Job Satisfaction Scale, a scale that was developed internally by the JHH research team, for their internal Culture Change Study.

is job satisfaction scale consisted of 10 items that re ected what it means to be satis ed professionally in this organization. Examples of questions include: "Would sta recommend services of JHH to a friend, or family member? Does the opinion of sta count? Does sta feel comfortable asking the help of their supervisor? Demonstration of respect was measured with the JHH Organizational Values Scale. is scale was developed internally by the JHH research team, for their internal Culture Change Study, and designed to re ect the sta value opinion of sta respect. is scale included 5 items that re ected what it meant to be respected in this environment.

e results indicated that four variables were found to be statistically associated with job satisfaction (univariate analyses). Logistic regression analyses identi ed respect as a signi cant predictor of job satisfaction, and this is presented for each of the thirteen units across the three sites of the organizations combined. e study participants were all nursing home sta , from 13 units
