

A Short Note on Aquaculture

James Brooks*

Department of Biology, The University of Alabama at Birmingham, Birmingham, AL, USA

Perspective

Aquaculture is breeding, raising, and harvesting fish, shellfish, and aquatic plants. Basically, it's farming in water. U.S. aquaculture is an environmentally responsible source of food and commercial products, helps to create healthier habitats, and is used to rebuild stocks of threatened or endangered species (1). Monoculture (less generally spelled pomology), also known as aquafarming, is the controlled civilization ("husbandry") of submarine organisms similar as fish, crustaceans, mollusks, algae and other organisms of value similar as submarine shops (e.g. lotus). Monoculture involves cultivating freshwater, brackish water, and saltwater populations under controlled or semi-natural conditions, and can be varied with marketable fishing, which is the harvesting of wild fish. (2) Mariculture, generally known as marine husbandry, refers specifically to monoculture rehearsed in seawater territories and lagoons, opposed to in brackish monoculture. Pisciculture is a type of monoculture that consists of the culturing of fish (fish husbandry) to gain fish and fish products as food. Monoculture can be conducted in fully artificial installations erected on land (onshore monoculture), as in the case of fish tank, ponds, aquaponics or courses, where the living conditions calculate on mortal control similar as water quality (oxygen), feed, temperature. Alternately, they can be conducted on well-sheltered shallow waters nearshore of a body of water (nearshore monoculture), where the cultivated species are subordinated to a fairly more natural surroundings; or on fended/ or semi-natural c037shinof
