### Letter

Childhood Disintegrative Disorder (CDD) is a rare and severe neurodevelopmental disorder characterized by a period of normal development followed by a significant regression in skills. The disorder is characterized by a loss of previously acquired skills in the areas of language, social interaction, and stereotyped behaviors. The regression typically occurs between the ages of 2 and 4 years, and is often accompanied by a loss of language skills and the emergence of stereotyped behaviors. The disorder is often associated with autism spectrum disorders and is considered a form of autism. The exact cause of CDD is unknown, but it is thought to be related to a combination of genetic and environmental factors. The disorder is often diagnosed through a combination of clinical observation and standardized testing. Treatment for CDD is typically focused on addressing the individual's specific needs and symptoms, and may include behavioral therapy, speech therapy, and medication. The prognosis for CDD is generally poor, with many individuals experiencing significant challenges throughout their lives.
